

[Tutorial] Human Genome Annotation

Tutorial for Tidyverse(Chapter 4)

1. Introduction

1.1. What is gene annotation?

Over the past years, we have learnt that there are a number of chromosomes and genes in our genome. Counting the number of chromosomes is fairly easy but students might find difficult to say how many genes we have in our genome. If you can get an answer for this, could you tell how many genes encode protein and how many do not?

To answer this question, we need to access the database for gene annotation. Gene annotation is the process of making nucleotide sequence meaningful - where genes are located? whether it is protein-coding or noncoding. If you would like to get an overview of gene annotation, please find this link.

One of well-known collaborative efforts in gene annotation is the GENCODE consortium. It is a part of the Encyclopedia of DNA Elements (The ENCODE project consortium) and aims to identify all gene features in the human genome using a combination of computational analysis, manual annotation, and experimental validation (Harrow et al. 2012). You might find another database for gene annotation, like RefSeq, CCDS, and need to understand differences between them.

Figure 1. Comparison of GENCODE and RefSeq gene annotation and the impact of reference geneset on variant effect prediction (Frankish et al. 2015). A) Mean number of alternatively spliced transcripts per multi-exon protein-coding locus B) Mean number of unique CDS per multi-exon protein-coding locus C) Mean number of unique (non-redundant) exons per multi-exon protein-coding locus D) Percentage genomic coverage of unique (non-redundant) exons at multi-exon protein-coding loci.

In this tutorial, we will access to gene annotation from the GENCODE consortium and explore genes and functional elements in our genome.

1.2. Aims

What we will do with this dataset:

- Be familiar with gene annotation modality.
- Tidy data and create a table for your analysis.
- Apply tidyverse functions for data munging.

Please note that there is better solution for getting gene annotation in R if you use a biomart. Our tutorial is only designed to have a practice on tidyverse exercise.

2. Explore your data

2.1. Unboxing your dataset

This tutorial will use a gene annotation file from the GENCODE. You will need to download the file from the GENCODE. If you are using terminal, please download file using wget:

```
# Run from your terminal, not R console  
# wget ftp://ftp.ebi.ac.uk/pub/databases/genocode/Gencode_human/release_31/genocode.v31.basic.annotation.gtf.gz  
  
# Once you downloaded the file, you won't need to download it again. So please comment out the command
```

Once you download the file, you can print out the first few lines using the following bash command (we will learn UNIX commands later):

```
# Run from your terminal, not R console  
#gzcat genocode.v31.basic.annotation.gtf.gz | head -7  
#zcat?
```

The file is the GFT file format, which you will find most commonly in gene annotation. Please read the file format thoroughly in the link above.

For the tutorial, we need to load two packages. If the package is not installed in your system, please install it.

-tidyverse, a package you have learnt from the chapter 5. -readr, a package provides a fast and friendly way to read. Since the file genocode.v31.basic.annotation.gtf.gz is pretty large, you will need some function to load data quickly into your workspace. readr in a part of tidyverse, so you can just load tidyverse to use readr functions.

Let's load the GTF file into your workspace. We will use read_delim function from the readr package. This is much faster loading than read.delim or read.csv from R base. However, please keep in mind that some parameters and output class for read_delim are slightly different from them.

```
library(tidyverse)
```

```
## -- Attaching packages ----- tidyverse 1.3.1 --
```

```
## v ggplot2 3.3.5      v purrr  0.3.4  
## v tibble  3.1.4      v dplyr  1.0.7  
## v tidyr   1.1.3      v stringr 1.4.0  
## v readr   2.0.1      v forcats 0.5.1
```

```
## -- Conflicts ----- tidyverse_conflicts() --  
## x dplyr::filter() masks stats::filter()  
## x dplyr::lag()    masks stats::lag()
```

```
d = read_delim('genocode.v31.basic.annotation.gtf.gz', delim='\t', skip = 5, progress = F, col_names = F)
```

```
## Rows: 1756502 Columns: 9
```

```
## -- Column specification -----
## Delimiter: "\t"
## chr (7): X1, X2, X3, X6, X7, X8, X9
## dbl (2): X4, X5

##
## i Use `spec()` to retrieve the full column specification for this data.
## i Specify the column types or set `show_col_types = FALSE` to quiet this message.
```

Can you find out what the parameters mean? Few things to note are:

- The GTF file contains the first few lines for comments (#). In general, the file contains description, provider, date, format.

- The GTF file does not have column names so you will need to assign 'FALSE' for col_names.

This is sort of canonical way to load your dataset into R. However, we are using a GTF format, which is specific to gene annotation so we can use a package to specifically handle a GTF file.

Here I introduce the package rtracklayer. Let's install the package first.

```
#if (!requireNamespace("BiocManager", quietly = TRUE))
#   install.packages("BiocManager")

#::install("rtracklayer")
```

Then, now you can read the GTF file using this package. Then, you can check the class of the object d.

```
d_26 = rtracklayer::import('gencode.v31.basic.annotation.gtf.gz')
```

```
class(d_26)
```

```
## [1] "GRanges"
## attr("package")
## [1] "GenomicRanges"
```

You will find out that this is GRanges class. This is from the package Genomic Range, specifically dealing with genomic datasets but we are not heading into this in this tutorial. So please find this information if you are serious on this.

We are converting d into a data frame as following:

```
d = d %>% as.data.frame()
```

Let's overview few lines from the data frame, and explore what you get in this object.

```
head(d)
```

```
##      X1      X2      X3      X4      X5 X6 X7 X8
## 1 chr1 HAVANA      gene 11869 14409 .  +  .
## 2 chr1 HAVANA transcript 11869 14409 .  +  .
## 3 chr1 HAVANA      exon 11869 12227 .  +  .
## 4 chr1 HAVANA      exon 12613 12721 .  +  .
```

```
## 5 chr1 HAVANA      exon 13221 14409 . + .
## 6 chr1 HAVANA transcript 12010 13670 . + .
##
## 1
## 2
## 3
## 4
## 5
## 6 gene_id "ENSG00000223972.5"; transcript_id "ENST00000456328.2"; gene_type "transcribed_unprocessed"
```

One thing you can find is that there is no columns in the data frame. Let's match which information is provided in columns. You can find the instruction page in the website ([link](#)).

Based on this, you can assign a name for 9 columns. One thing to remember is you should not use space for the column name. Spacing in the column name is actually working but not a good habit for your code. So please replace a space with underscore in the column name.

```
# Assign column names according to the GENCODE instruction.
cols = c('chrom', 'source', 'feature_type', 'start', 'end', 'score', 'strand', 'phase', 'info')
```

Now you can set up the column names into the `col_names` parameter, and load the file into a data frame.

```
d = read_delim('gencode.v31.basic.annotation.gtf.gz',
               delim='\t', skip = 5,
               progress = F,
               col_names = cols)
```

```
## Rows: 1756502 Columns: 9
```

```
## -- Column specification -----
## Delimiter: "\t"
## chr (7): chrom, source, feature_type, score, strand, phase, info
## dbl (2): start, end

##
## i Use `spec()` to retrieve the full column specification for this data.
## i Specify the column types or set `show_col_types = FALSE` to quiet this message.
```

You can find the column names are now all set.

```
head(d)
```

```
## # A tibble: 6 x 9
##   chrom source feature_type start   end score strand phase info
##   <chr> <chr>   <chr>      <dbl> <dbl> <chr> <chr>  <chr> <chr>
## 1 chr1  HAVANA  gene        11869 14409 .    +    .    "gene_id \"ENSG000000~
## 2 chr1  HAVANA  transcript   11869 14409 .    +    .    "gene_id \"ENSG000000~
## 3 chr1  HAVANA  exon        11869 12227 .    +    .    "gene_id \"ENSG000000~
## 4 chr1  HAVANA  exon        12613 12721 .    +    .    "gene_id \"ENSG000000~
## 5 chr1  HAVANA  exon        13221 14409 .    +    .    "gene_id \"ENSG000000~
## 6 chr1  HAVANA  transcript   12010 13670 .    +    .    "gene_id \"ENSG000000~
```

When you loaded the file, you see the message about the data class. You might want to overview this data.

```
summary(d)
```

```

```

2.2. How many feature types in the GENCODE dataset?

As instructed in the GENCODE website, the GENCODE dataset provides a range of annotations for the feature type. You can check feature types using _____ function.

```
d %>% group_by(feature_type) %>% count(feature_type)
```

```
## # A tibble: 8 x 2
## # Groups:   feature_type [8]
##   feature_type      n
##   <chr>          <int>
## 1 CDS            567862
## 2 exon           744835
## 3 gene           60603
## 4 Selenocysteine    96
## 5 start_codon      57886
## 6 stop_codon       57775
## 7 transcript       108243
## 8 UTR             159202
```

```
#table(d$feature_type)
```

8 feature types *Selenocysteine :Selenocysteine is produced when the UGA codon, which is normally recognized as a stop codon, is translated into a specific pathway. Selenocysteine, the 21st amino acid, has been found in 25 human selenoproteins and selenoenzymes important for fundamental cellular processes ranging from selenium homeostasis maintenance to the regulation of the overall metabolic rate.

2.3. How many genes we have?

Let's count the number of genes in our genome. Since we know that the column `feature_type` contains rows with gene, which contains obviously annotations for genes. We might want to subset those rows from the data frame.

```
d1 = filter(d, feature_type == 'gene')  
  
#d1 = d[d$feature_type == 'gene', ]
```

2.4. Ensembl, Havana and CCDS.

Gene annotation for the human genome is provided by multiple organizations with different gene annotation methods and strategy. This means that information can be varying by resources, and users need to understand heterogeneity inherent in annotation databases.

The GENCODE project utilizes two sources of gene annotation.

1. Havana: Manual gene annotation (detailed strategy in here)
2. Ensembl: Automatic gene annotation (detailed strategy in here)

It provides the combination of Ensembl/HAVANA gene set as the default gene annotation for the human genome. In addition, they also guarantee that all transcripts from the Consensus Coding Sequence (CCDS) set are present in the GENCODE gene set. The CCDS project is a collaborative effort to identify a core set of protein coding regions that are consistently annotated and of high quality. Initial results from the Consensus CDS (CCDS) project are now available through the appropriate Ensembl gene pages and from the CCDS project page at NCBI. The CCDS set is built by consensus among Ensembl, the National Center for Biotechnology Information (NCBI), and the HUGO Gene Nomenclature Committee (HGNC) for human (link).

Right. Then now we count how many genes annotated with HAVANA and ENSEMBL.

```
d %>% group_by(source) %>% count(source)  
  
## # A tibble: 2 x 2  
## # Groups:   source [2]  
##   source      n  
##   <chr>    <int>  
## 1 ENSEMBL 245185  
## 2 HAVANA  1511317
```

2.5. do.call

Since the last column `info` contains a long string for multiple annotations, we will need to split it to extract each annotation. For example, the first line for transcript annotation looks like this:

```
#chr1    HAVANA    transcript    11869    14409    .    +    .    gene_id "ENSG00000223972.5"; transcrip
```

If you would like to split `transcript_support_level` and create a new column, you can use `strsplit` function.

```
a = 'chr1 HAVANA transcript 11869 14409 . + . gene_id "ENSG00000223972.5"; trans
strsplit(a, 'transcript_support_level\\s+')

```

```
## [[1]]
## [1] "chr1 HAVANA transcript 11869 14409 . + . gene_id \"ENSG00000223972.5\"";
## [2] "1\"; hgnc_id \"HGNC:37102\"; tag \"basic\"; havana_gene \"OTTHUMG00000000961.2\"; havana_transc

```

After split the string, you can select the second item in the list ([[1]][2]).

```
strsplit(a, 'transcript_support_level\\s+')[[1]][2]

```

```
## [1] "1\"; hgnc_id \"HGNC:37102\"; tag \"basic\"; havana_gene \"OTTHUMG00000000961.2\"; havana_transc

```

You can find the 1 in the first position, which you will need to split again.

```
b = strsplit(a, 'transcript_support_level\\s+')[[1]][2]
strsplit(b, '\\')

```

```
## [[1]]
## [1] "1" "HGNC:37102"
## [4] "; tag " "basic" "; havana_gene "
## [7] "OTTHUMG00000000961.2" "; havana_transcript " "OTTHUMT00000362751.1"
## [10] "; "

```

From this, you will get the first item in the list ([[1]][1]).

Now you would like to apply strsplit function across vectors. For this, do.call function can be easily implemented to strsplit over the vectors from one column. Let's try this.

```
head(do.call(rbind.data.frame, strsplit(a, 'transcript_support_level\\s+'))[[2]])

```

```
## [1] "1\"; hgnc_id \"HGNC:37102\"; tag \"basic\"; havana_gene \"OTTHUMG00000000961.2\"; havana_transc

```

Now you can write two lines of codes to process two steps we discussed above.

```
# First filter transcripts and create a data frame.
d2 <- d %>% filter(feature_type == 'transcript')

# Now apply the functions.
d2$transcript_support_level <- as.character(do.call(rbind.data.frame,
  strsplit(d2$info, 'transcript_support_level\\s+'))[[2]])

d2$transcript_support_level <- as.character(do.call(rbind.data.frame,
  strsplit(d2$transcript_support_level, '\\'))[[1]])

```

Now you can check the strsplit works.

```
head(d2$transcript_support_level)
```

```
## [1] "1" "NA" "NA" "NA" "5" "5"
```

You can use the same method to extract other annotations, like `gene_id`, `gene_name` etc.

3. Exercises

Here I list the questions for your activity. Please note that it is an exercise for tidyverse functions, which you will need to use in your code. In addition, you will need to write an one-line code for each question using pipe `%>%`.

For questions, you should read some information thoroughly, including:

- Gene biotype.
- 0 or 1 based annotation in GTF, BED format.
- Why some features have 1 bp length?
- What is the meaning of zero-length exons in GENCODE? Also fun to have a review for microexons
- Transcript support level (TSL)

3.1. Annotation of transcripts in our genome

1. Computes the number of transcripts per gene. What is the mean number of transcripts per gene? What is the quantile (25%, 50%, 75%) for these numbers? Which gene has the greatest number of transcript?

```
library(dplyr)
d_26 <- as.data.frame(d_26)
d_id <- d_26 %>%
  select(seqnames, source, type, start, end, score, strand, phase, gene_id)
```

```
trans <- d_id %>% group_by(gene_id) %>%
  filter(type == "transcript") %>%
  count()
```

```
trans
```

```
## # A tibble: 60,603 x 2
## # Groups:   gene_id [60,603]
##   gene_id          n
##   <chr>         <int>
## 1 ENSG00000000003.14      3
## 2 ENSG00000000005.6       1
## 3 ENSG000000000419.12     2
## 4 ENSG000000000457.14     3
## 5 ENSG000000000460.17     5
## 6 ENSG000000000938.13     3
## 7 ENSG000000000971.15     3
```

```
## 8 ENSG00000001036.13      1
## 9 ENSG00000001084.13      5
## 10 ENSG00000001167.14     2
## # ... with 60,593 more rows
```

```
mean(trans$n)
```

```
## [1] 1.7861
```

```
c <- trans$n
quantile(c, c(0.25, 0.50, 0.75))
```

```
## 25% 50% 75%
##    1    1    2
```

```
trans$gene_id[[which.max(trans$n)]]
```

```
## [1] "ENSG00000109339.22"
```

2. Compute the number of transcripts per gene among gene biotypes. For example, compare the number of transcript per gene between protein-coding genes, long noncoding genes, pseudogenes.

```
s <- d_26 %>% group_by(gene_type, gene_id) %>%
  filter(type == "transcript") %>%
  count()
```

```
s %>% arrange(gene_type)
```

```
## # A tibble: 60,603 x 3
## # Groups:   gene_type, gene_id [60,603]
##   gene_type gene_id      n
##   <chr>      <chr>    <int>
## 1 IG_C_gene ENSG00000211592.8    1
## 2 IG_C_gene ENSG00000211675.2    1
## 3 IG_C_gene ENSG00000211677.2    1
## 4 IG_C_gene ENSG00000211679.2    1
## 5 IG_C_gene ENSG00000211685.3    1
## 6 IG_C_gene ENSG00000211890.4    1
## 7 IG_C_gene ENSG00000211891.6    1
## 8 IG_C_gene ENSG00000211892.4    1
## 9 IG_C_gene ENSG00000211893.4    1
## 10 IG_C_gene ENSG00000211895.5    1
## # ... with 60,593 more rows
```

```
#mean
s %>% group_by(gene_type) %>%
  summarise(m_transcripts = mean(n))
```

```
## # A tibble: 40 x 2
##   gene_type      m_transcripts
##   <chr>          <dbl>
## 1 IG_C_gene      1
## 2 IG_C_pseudogene 1
## 3 IG_D_gene      1
## 4 IG_J_gene      1
## 5 IG_J_pseudogene 1
## 6 IG_pseudogene   1
## 7 IG_V_gene      1
## 8 IG_V_pseudogene 1
## 9 lncRNA          1.48
## 10 miRNA          1
## # ... with 30 more rows
```

```
#quantile(0%, 25%, 50%, 75%, 100%)
s %>% group_by(gene_type) %>%
  summarise(Quantile = quantile(n, c(0.00, 0.25, 0.50, 0.75, 1.00)), q = c(0.00, 0.25, 0.50, 0.75, 1.00))
```

```
## # A tibble: 200 x 3
## # Groups:   gene_type [40]
##   gene_type      Quantile      q
##   <chr>          <dbl> <dbl>

## 2 IG_C_gene      1 0.25
## 3 IG_C_gene      1 0.5
## 4 IG_C_gene      1 0.75
## 5 IG_C_gene      1 1
## 6 IG_C_pseudogene 1 0
## 7 IG_C_pseudogene 1 0.25
## 8 IG_C_pseudogene 1 0.5
## 9 IG_C_pseudogene 1 0.75
## 10 IG_C_pseudogene 1 1
## # ... with 190 more rows
```

3. Final task is to compute the number of transcripts per gene per chromosome.

```
l <- d_26 %>% group_by(seqnames, gene_type, gene_id) %>%
  filter(type == "transcript") %>%
  count()

l
```

```
## # A tibble: 60,603 x 4
## # Groups:   seqnames, gene_type, gene_id [60,603]
##   seqnames gene_type      gene_id      n
##   <fct>    <chr>          <chr>    <int>
## 1 chr1     IG_V_pseudogene ENSG00000276674.1 1
## 2 chr1     lncRNA           ENSG00000116652.6 1
## 3 chr1     lncRNA           ENSG00000116883.8 1
## 4 chr1     lncRNA           ENSG00000117242.7 1
## 5 chr1     lncRNA           ENSG00000153363.13 9
```

```

3.2. Gene length in the GENCODE

1. What is the average length of human genes?

```
mean(d_26$width)
```

```
## [1] 4069.518
```

2. Is the distribution of gene length differed by autosomal and sex chromosomes? Please calculate the quantiles (0%, 25%, 50%, 75%, 100%) of the gene length for each group.

```
d_chrtype <- d_26 %>%  
  filter(seqnames != "chrM") %>%  
  mutate(chr_type = case_when(  
    seqnames %in% c("chrX", "chrY") ~ "sex",  
    TRUE ~ "autosomal"  
  ))
```

```
d_chrtype %>% group_by(chr_type) %>%  
  summarise(Quantile = quantile(width, c(0.00, 0.25, 0.50, 0.75, 1.00)), .groups = "keep") %>%  
  mutate(q = c(0.00, 0.25, 0.50, 0.75, 1.00))
```

```
## # A tibble: 10 x 3  
## # Groups:   chr_type [2]  
##   chr_type Quantile    q  
##   <chr>      <dbl> <dbl>  
## 1 autosomal      1  0  
## 2 autosomal     80 0.25

## 9 sex         230 0.75  
## 10 sex        2241765 1
```

3. Is the distribution of gene length differed by gene biotype? Please calculate the quantiles (0%, 25%, 50%, 75%, 100%) of the gene length for each group.

```
d_26 %>% group_by(gene_type) %>%  
  summarise(Quantile = quantile(width, c(0.00, 0.25, 0.50, 0.75, 1.00)), .groups = "keep") %>%  
  mutate(q = c(0.00, 0.25, 0.50, 0.75, 1.00))
```

```
## # A tibble: 200 x 3  
## # Groups:   gene_type [40]  
##   gene_type Quantile    q  
##   <chr>      <dbl> <dbl>  
## 1 IG_C_gene      3  0  
## 2 IG_C_gene     92 0.25

## 10 IG_C_pseudogene     5211  1
## # ... with 190 more rows
```

3.3. Transcript support levels (TSL)

The GENCODE TSL provides a consistent method of evaluating the level of support that a GENCODE transcript annotation is actually expressed in humans.

1. With transcript, how many transcripts are categorized for each TSL?

```
d_26 %>% group_by(transcript_support_level) %>%
  filter(type == "transcript") %>%
  count()
```

```
## # A tibble: 7 x 2
## # Groups:   transcript_support_level [7]
##   transcript_support_level     n
##   <chr>                  <int>
## 1 1                      31801
## 2 2                      13372
## 3 3                       7228
## 4 4                       2245
## 5 5                     13674
## 6 NA                    27843
## 7 <NA>                   12080
```

2. From the first question, please count the number of transcript for each TSL by gene biotype.

```
d_26 %>% group_by(gene_type, transcript_support_level) %>%
  filter(type == "transcript") %>%
  count()
```

```
## # A tibble: 91 x 3
## # Groups:   gene_type, transcript_support_level [91]
##   gene_type      transcript_support_level     n
##   <chr>          <chr>                  <int>
## 1 IG_C_gene      1                      1
## 2 IG_C_gene      5                      1
## 3 IG_C_gene      NA                      7
## 4 IG_C_gene      <NA>                   5
## 5 IG_C_pseudogene NA                      9
## 6 IG_D_gene      NA                     37
## 7 IG_J_gene      NA                     18
## 8 IG_J_pseudogene NA                     3
## 9 IG_pseudogene  NA                     1
## 10 IG_V_gene      5                      3
## # ... with 81 more rows
```

3. From the first question, please count the number of transcript for each TSL by source.

```
d_26 %>% group_by(source, transcript_support_level) %>%
  filter(type == "transcript") %>%
  count()
```

```
## # A tibble: 14 x 3
## # Groups:   source, transcript_support_level [14]
##   source transcript_support_level     n
##   <fct>   <chr>                  <int>
## 1 HAVANA  1                      29434
## 2 HAVANA  2                      12052
## 3 HAVANA  3                       6964
## 4 HAVANA  4                       2116
## 5 HAVANA  5                      10157
## 6 HAVANA NA                      19962
## 7 HAVANA <NA>                   11901
## 8 ENSEMBL 1                      2367
## 9 ENSEMBL 2                      1320
## 10 ENSEMBL 3                       264
## 11 ENSEMBL 4                       129
## 12 ENSEMBL 5                     3517
## 13 ENSEMBL NA                     7881
## 14 ENSEMBL <NA>                   179
```

3.4. CCDS in the GENCODE

1. With gene, please create a data frame with the columns - gene_id, gene_name, hgnc_id, gene_type, chromosome, start, end, and strand. Then, please create new columns for presence of hgnc and ccids. For example, you can put 1 in the column isHgnc, if hgnc annotation is available, or 0 if not. Then, you can put 1 in the column isCCDS, if ccids annotation is available, or 0 if not.

```
d_3.4 <- d_26 %>%
  select(gene_id, gene_name, hgnc_id, gene_type, seqnames, start, end, strand) %>%
  mutate(isHgnc = case_when(
    is.na(hgnc_id) ~ "0",
    TRUE ~ "1")
  ) %>%
  mutate(isCCDS = case_when(
    is.na(d_26$ccdsid) ~ "0",
    TRUE ~ "1")
  )
```

2. Please count the number of hgnc by gene biotypes.

```
d_3.4 %>% filter(isHgnc == "1") %>%
  group_by(gene_id, gene_type) %>%
  count() %>% ungroup() %>% group_by(gene_type) %>%
  count()
```

```
## # A tibble: 36 x 2
## # Groups:   gene_type [36]
##   gene_type     n
```

```
##   <chr>          <int>
## 1 IG_C_gene      14
## 2 IG_C_pseudogene 9
## 3 IG_D_gene      37
## 4 IG_J_gene      18
## 5 IG_J_pseudogene 3
## 6 IG_V_gene      142
## 7 IG_V_pseudogene 185
## 8 lncRNA          3970
## 9 miRNA           1856
## 10 misc_RNA       1033
## # ... with 26 more rows
```

3. Please count the number of hgnc by level. Please note that level in this question is not TSL. Please find information in this link: 1 (verified loci), 2 (manually annotated loci), 3 (automatically annotated loci).

```
d_3.4.3 <- d_26 %>%
  mutate(isHgnc = case_when(
    is.na(hgnc_id) ~ "0",
    TRUE ~ "1")
  )
```

```
d_3.4.3 %>%
  filter(isHgnc == "1") %>%
  group_by(level) %>%
  count()
```

```
## # A tibble: 3 x 2
## # Groups:   level [3]
##   level      n
##   <chr>   <int>
## 1 1       107054
## 2 2       1279964
## 3 3       237265
```

#without creating "isHgnc" column, using grepl()

```
d_26 %>% filter(grepl("HGNC", d_26$hgnc_id) == TRUE) %>%
  group_by(level) %>% count()
```

```
## # A tibble: 3 x 2
## # Groups:   level [3]
##   level      n
##   <chr>   <int>
## 1 1       107054
## 2 2       1279964
## 3 3       237265
```

3.5. Transcripts in the GENCODE

1. Which gene has the largest number of transcripts?

```
trans$gene_id[[which.max(trans$n)]]
```

```
## [1] "ENSG00000109339.22"
```

2. Please calculate the quantiles (0%, 25%, 50%, 75%, 100%) of the gene length for protein coding genes and long noncoding genes.

```
d_26 %>% filter(gene_type %in% c("protein_coding", "lncRNA")) %>%
group_by(gene_type) %>%
  summarise(Quantile = quantile(width, c(0.00, 0.25, 0.50, 0.75, 1.00)), .groups = "keep") %>%
  mutate(q = c(0.00, 0.25, 0.50, 0.75, 1.00))
```

```
## # A tibble: 10 x 3
## # Groups:   gene_type [2]
##   gene_type      Quantile      q
##   <chr>          <dbl> <dbl>
## 1 lncRNA           1  0
## 2 lncRNA          126 0.25
## 3 lncRNA          339 0.5
## 4 lncRNA         2658 0.75
## 5 lncRNA       1375317  1
## 6 protein_coding     1  0
## 7 protein_coding     76 0.25
## 8 protein_coding    123 0.5
## 9 protein_coding    193 0.75
## 10 protein_coding 2473537  1
```

3. Please count the number of transcripts by chromosomes.

```
d_26 %>%
  filter(type == "transcript") %>%
  group_by(seqnames) %>%
  count()
```

```
## # A tibble: 25 x 2
## # Groups:   seqnames [25]
##   seqnames      n
##   <fct>    <int>
## 1 chr1      9827
## 2 chr2      7432
## 3 chr3      6157
## 4 chr4      4662
## 5 chr5      5203
## 6 chr6      5455
## 7 chr7      5292
## 8 chr8      4350
## 9 chr9      3949
## 10 chr10     4157
## # ... with 15 more rows
```

3.6. Autosomal vs. Sex chromosomes.

1. Please calculate the number of genes per chromosome.

```
d_26 %>% filter(type == "gene") %>%
  group_by(seqnames) %>%
  count()
```

```
## # A tibble: 25 x 2
## # Groups:   seqnames [25]
##   seqnames      n
##   <fct>    <int>
## 1 chr1      5471
## 2 chr2      4196
## 3 chr3      3185
## 4 chr4      2651
## 5 chr5      2983
## 6 chr6      3059
## 7 chr7      3014
## 8 chr8      2482
## 9 chr9      2327
## 10 chr10     2332
## # ... with 15 more rows
```

2. Please compare the number of genes between autosomal and sex chromosome (Mean, Median).

```
d_chrtype %>% filter(type == "gene") %>%
  group_by(seqnames, chr_type) %>%
  count() %>% ungroup() %>%
  group_by(chr_type) %>%
  summarise(Mean = mean(n), Median = median(n))
```

```
## # A tibble: 2 x 3
##   chr_type    Mean Median
##   <chr>    <dbl>  <dbl>
## 1 autosomal 2617.  2604.
## 2 sex      1494.  1494.
```

3. Please divide the genes into groups 'protein coding' and 'long noncoding', and then compare the number of genes in each chromosomes within groups.

```
d_26 %>% filter(type == "gene" & gene_type %in% c("protein_coding", "lncRNA")) %>%
  group_by(seqnames, gene_type) %>%
  count()
```

```
## # A tibble: 49 x 3
## # Groups:   seqnames, gene_type [49]
##   seqnames gene_type      n
##   <fct>    <chr>    <int>
## 1 chr1    lncRNA      1416
## 2 chr1    protein_coding 2048
```

```
## 3 chr2    lncRNA      1241
## 4 chr2    protein_coding 1247
## 5 chr3    lncRNA      861
## 6 chr3    protein_coding 1075
## 7 chr4    lncRNA      790
## 8 chr4    protein_coding 751
## 9 chr5    lncRNA      950
## 10 chr5   protein_coding 886
## # ... with 39 more rows
```
